## 2017

20th Annual High School Mathematical Contest in Modeling (HiMCM) Summary Sheet
Team Control Number: 8062
Problem Chosen: A
The flying of drone is a popular aerial performance now. The difficulty is that we need to design flight pattern, flight routes, and other flight parameters before performing, that we discussion around those.

Firstly, we get the drone distribution according to the image processing function of MATLAB. For simple patterns (such as Ferris wheel), we find each of the marginal functions and length in the pattern, and assign the drone equally according to the total length of the pattern. For complex images (such as dragon), because can't figure out each of the marginal functions in the pattern, we through the MATLAB transformed into the RGB matrix and then transformed into 0-1 matrix, and then pick the edge pixel of the image, and then according to the distance between the edge pixel points, all the edge pixel points are ordered and the fixed number of drone is distributed according to the sorting results.

And then we choose $300,400 \ldots \ldots .1000$ drones, and look at the effect of the final impression drawing, found that when the number of drones increased to $500-600$, the effect of the image is not obvious increase. Therefore, we select the 500 drones which given in the topic for further research. Among them, the flight area of drone is calculated by drone distribution and the distance between adjacent drones can not be greater than 2 meters; the safety factors of drone mainly consider the two factors of drone internal GPS positioning error and external environment factors; drone flight time includes: drone ascent stage, image conversion stage, image rotation phase, descent stage, light duration or intermittent flicker stage.

Finally, we select several images to validate our model, and we conclude that our model is more suitable for images with more smooth edges. The advantage of our model is that we can change any number of drones and any patterns, and then quickly get the position $\left(x_{i}, y_{i}, z_{i}\right)$ of the drone, but our model needs to pre-process the image.

## 1 Introduction

### 1.1 Background

Drones not only evince the advanced development of our country, they can also provide us with some significant aerial light shows when numerous colorful drones flying into the air during the quiet night. In 2015, Intel has already devised 100 Shooting Star ${ }^{\mathrm{TM}}$ drones and performed wonderful aerial light shows. When drones lit up to the air and merged with the celeste skies and warm sunshine, we were moved by significant visual impacts. After eight months in 2016, they showed this spectacle again by making efficient use of five hundred drones, broking the past records as well as creating new Guinness World Records. Nowadays, aimed to celebrate our city's important festival, we are supposed to design an outdoor aerial show, which includes three different possible performances made by multitudinous drones.

### 1.2 Problems

For the sake of congratulating a yearly ceremony, we are required to provide the conception of using drones to create three possible light show displays.

In order to ensure the successful procession during three shows:
(a) Ferris
( b ) Dragon
( c ) Create your own image
We should:
( a ) Build models to determine the required number of Drones and every Drone's initial location during the process
( b ) Apply mathematical methods to make sure the flight route of every Drone and the setting of drone. Then describe the flight routes according to mathematical language.

Write a two-page memo to the Mayor to report the results of your investigation and make a recommendation as to whether or not to do the aerial light show.

## 2 Justification of our model

In order to better understand the topic background, just in Wuhan, China on November 4, there is a world conference on flight assembly of unmanned aerial vehicle (drone) cluster light show, I and my team to watch the flight assembly, in the watch, we get the following conclusion: First of all, all of drones lined as a square in the ground. And then, they hovered into the sky in batches according to the command. After arriving in the specified height, their lights were illuminated and they stayed in their own position for a moment in order to present the pattern for spectators. Next, they turned into the icon of Intel on the basis of track, which was set in advance. They moved in different time period, dividing into several regions. Every drone is inclined into disparate degrees so that spectators can see various shapes from diverse
angel. When drones reached the visual effect, they descended in order and finished the show.

Based on the requirements and information mentioned in 1.2, when drones are controlled and performed, there are several following challenges that need to be fixed. First, we need to identify the location of each drone. For simple-shape design, drones are arranged in the shape of the design. After graphing design, we calculate the length of each side. And then we use plot, instead of line, to construct outline of the design. The location of each drone is the plot. The increasing complexity of the image leads to the difficulty to plot each drone. We plan to the complex, colored image by forming $0-1$ matrix so that edges are simplified into white or black plots. Then, the program will search for the first black plot, and then find the closest black plot with certain distance the second one, and finally get required plots, which are the locations of drones.

Second, when the drones need to be reshaped in the sky, they might crash. Drones are divided into several batches to take off and rise up to different height. Drones in the same height move along the same direction at the same time roughly.

These five pictures represent 'The drone is distributed on the ground', 'Drones rise in batches', 'The drone light can be switched on the air', 'The drone moves in batches',
'Drones rotate to different angles' respectively.

## 3 Assumptions

(1)Assuming that the three performances are continuous, there is no drone falling and then ascending in midway.
(2)Assuming that the drone GPS positioning error uses a more advanced double star
positioning, positioning error is only 1 meters。
(3)Assuming that there is no cooperative action between drones, that is, the action between each drone does not affect the action of other drones.
(4)Assuming that the distance from the audience to the performance area in the different directions is equal, because the time is limited, and the calculation is simplified.

## 4 THE MODEL

### 4.1 Image contour

### 4.1.1 Mathematical expression for simple graph

Graph of Ferris Wheel is composed of the simple functional graphs such as lines and circles. In this way, we need to determine the expressions of these circles and lines, and their perimeters. The structure of the Ferris Wheel, "The London Eye", can be roughly drafted as mathematical functional figures shown in Fig.1. The cars are referred to as outer circles; the frame is referred to as inner circles and inner lines; and the pedestal is referred to as stanchion lines.

Fig. 1 functional expression of The London Eye
Assume that the center of circles is origin. And $R_{C 1}, R_{C 2}$ are the radii of two outer circles, and $C_{1}, C_{2}$ are represented as the perimeter of the outer circles. The parametric equation of the inner circles is shown following,

$$
\left\{\begin{array}{c}
\left.x=\sin \frac{2 \pi}{t} \cdot m\right) \cdot \frac{i}{n+1} \cdot R_{1} \\
\left.y=\cos \frac{2 \pi}{t} \cdot m\right) \cdot \frac{i}{n+1} \cdot R_{1} \\
\left\{\begin{array}{c}
m=1,2,3, \ldots, t \\
i=1,2,3, \ldots, n
\end{array}\right.
\end{array}\right.
$$

where $x$ and $y$ are the coordinates of every point at the inner circles; t is the number of drones in one inner circle; and n is number of circles inside. By joining the points in one line which passes through the origin, the inner lines could be derived. And the expression of stanchion line could be estimated as a linear function which could by estimating the slope (the slant angle of the pedestal mostly is around $15^{\circ}$ ) according to the reality. And comparing with the most Ferris Wheels' pictures, it can be measured that the ratio between $R_{C 1}$ and $R_{C 2}$ is nearly 1.1 (such as for The London Eye, the ratio is $135: 122=1.106^{2}$ ). By using the MATLAB, the distribution graph of the drone swarm could be realized, shown in Fig. 2 following, which the larger points represent the higher brightness.

Fig. 2 Ferris Wheel Plan
In addition, the amount of drones and their distribution can be obtained by parameterization. Assume that the numbers of drones at each inner circles are $\mathrm{N}_{l}, \mathrm{~N}_{2}$, $\mathrm{N}_{3}, \ldots \mathrm{~N}_{i}$ and the radii of each circle are $\mathrm{R}_{1}, \mathrm{R}_{2}, \mathrm{R}_{3}, \ldots \mathrm{R}_{i}$, respectively. Defining the drones' density:

$$
\rho=\frac{N_{i}}{R_{i}}
$$

From the deeper research, errors caused by GPS positioning lead to the minimum safe distance between two normal drones that is around 3 to 5 meters. Thus, every two points in the functional graph should be less than this distance.

When in the real performance, the drone swarms are flied in three dimension. But the movement of each drone is in one dimension. So for every performance pattern, first we could draw the 2-D mathematical image, then slope it in an angle which could enjoy the spectators best (specifically illustrate at 2.1 ). Assuming the view angle is $30^{\circ}$, the MATLAB simulates the image shown in Fig. 3. a \& b.

Fig. 3 a. \& b. show the Ferris-Wheel-shaped function realized in 3-D
The cost and the aesthetics are also the significant consideration of designing. The less drones with more beauty, the better design it is. By changing the number of drones in the outer circles and in the pedestals, we could make trade-off. Several comparison diagrams are shown in Fig.4:

Thirty-six Drones in Each Outer Circle \& Nine Drone for each Pedestal

Sixty Drones in Each Outer Circle \& Eleven Drones for each Pedestal
ory Drones in Each Outer Circle \& Eleven Drones for each Pedestal

Fig. 4 different numbers of drones in Outer Circles and Pedestals
The second scheme is what we represent: forty drones in each outer circles, twelve drones in each inner circles, nine drones for each pedestal, thirty degrees for the slant angle of two pedestal, and thirty degrees for the angle of inclination in three dimension.

### 4.1.2 Mathematical expressions of complex graphs

### 4.1.2.1The preprocessing of the image

As for the complex image, like the image of dragon, we need to preprocess the image first. After finding an image of dragon, we preprocess the image into
amonochrome image. In order to diminish distraction image, like fig 3, We consider two scenarios: (1) only the pattern of edge information, (2) contains the design of the interior elements

Fig 5

### 4.1.2.2 Image binaryzation

The arrangement of drones is usually along the edge of the image. If we use gray matrix, the pixel value cannot be identified. Therefore, we use threshold matrix to identify the pixels in the image.

According to knowledge related to computer graphics, we need to handle the image before we divide the pixels that represent the image of dragon and the pixels that represent other things. Normally, through grey processing, we regulate the range of the pixel value from 0 to 255 . Then, we set up the threshold value to divide the pixels that represent the image of dragon and the pixels that represent other things
In addition, for a monochrome image, we only need to divide the image into white area and black area.

In order to express the pixels that represent the image of dragon and the pixels that represent other things, we use MATLAB to preprocess the image. First, the image is imported into MATLAB, and MATLAB generate corresponding pixel matrix. According to the knowledge related to computer graphics, the RGB of white area is 255. In order to make the image feature clearer, it's necessary to use image threshold method, showed in the following equations.

$$
Q= \begin{cases}0, & q_{i j} \geq 150 \\ 1, & q_{i j}<150\end{cases}
$$

Attention: We convert the elements greater than 150 to 0 , and convert less than 150 to 1 , the purpose is to make the original white image turn black (like the night sky), the original edges will become white (like light colors) and can be assigned different colors after the MATLAB imshow function.

In the equations, $q \mathrm{ij}$ represents the pixel value before image threshold; $\mathrm{P}_{\mathrm{ij}}$ represents the pixel value after image threshold.

Through image threshold, a series of pixel value matrix are produced, which can be used for image feature extraction.

### 4.1.2.3 Image edge information extraction

For the picture in Figure 4, we need to extract the edge information. For the picture in Figure 3, we need to delete the redundant edge information. So we all have a process of extracting edge information. There are many ways to extract the edge
information, but they are all very complex. Here we think of a relatively simple method of edge information extraction:

For $p_{i j}, d_{i j}$ represent the corresponding gray matrix of the initial image and the corresponding matrix of the edge image respectively. And $p_{i j}, d_{i j}$ are all $0-1$ matrices. The principle of extraction is :
$\left(\begin{array}{ccccc}p_{11} & & & & p_{1 n} \\ & p_{(i-1)(j-1)} & p_{(i-1) j} & p_{(i-1)(j+1)} & \\ & p_{i(j-1)} & p_{i j} & p_{i(j+1)} & \\ & p_{(i+1)(j-1)} & p_{(i+1) j} & p_{(i+1)(j+1)} & \\ p_{m 1} & & & & p_{m n}\end{array}\right) \Rightarrow\left(\begin{array}{ccccc}d_{11} & & & & d_{1 n} \\ & d_{(i-1)(j-1)} & d_{(i-1) j} & d_{(i-1)(j+1)} & \\ & d_{i(j-1)} & d_{i j} & d_{i(j+1)} & \\ & d_{(i+1)(j-1)} & d_{(i+1) j} & d_{(i+1)(j+1)} & \\ d_{m 1} & & & & d_{m n}\end{array}\right)$

- If $p_{i j}=0$, then $d_{i j}=0$

If $p_{i j}$ represents the outside region, then $d_{i j}$ is consistent with $p_{i j}$

- If $p_{i j}=1$ and $\forall\left(p_{(i+1) j}=0, p_{i(j-1)}=0, p_{(i-1) j}=0, p_{i(j+1)}=0\right)$, then $d_{i j}=0$

If $p_{i j}$ represents an internal region, then $d_{i j}$ does not agree with $p_{i j}$

- If $p_{i j}=1$ and $\exists\left(p_{(i+1) j}=0, p_{i(j-1)}=0, p_{(i-1) j}=0, p_{i(j+1)}=0\right)$, then $d_{i j}=1$

If $p_{i j}$ represents the edge region, then $d_{i j}$ is in line with $p_{i j}$
After handling the above principles, we have heard that MATLAB is different

Fig6.
According to the principle of extraction, we can achieve extracting Fig5. by using MATLAB, and the extracting figure compared to the previous figure that are not be extracted show at figure.

We used MATLAB to find out that there are 2328/2374 pixels in the image above. Since the number of Drones is limited, it cannot reach $2328 / 2374$ so I need to choose $N$ pixels from an average of 2328/2374 pixels. $N$ is the number of dones.

### 4.1.2.3 Rank the edge pixels

In this part, we choose a method called average selection. Average selection does not mean choosing at random or choosing at the standard of horizontal and vertical, and it means choosing on the basis of the edge length of pixels, but the edge of pixels is too difficult to calculate. Therefore, we need to rank the pixels.

Choose the initial point (the left-most point at top)
We can use matrix B and check from one line. If it exits 1 , that point is the initial point, and if it does not exist, we can check continually.

We can calculate the distance from other points to initial point, and find the point that has the nearest distance, so this one is the second point. We can find other points through circulation by imitating the preceding procedure, and this circulation has eight hundred and ninety times.

This process can be depicted by the following flow chart. We can locate the position of drones by average choosing five hundred points from 2328 or 2374 points. The 2D expression to show the coordinate of drones is $\left(x_{i}, y_{i}\right)$.

### 4.2 Three Displays

We have to design three different images, the first image is Ferris wheel (can be expressed by function); the second is the dragon (the edge of the image is not smooth);
the third we choose the panda with Chinese characteristics (smooth edge of the image)

Fig7. The panda image

### 4.2.1Determination of the number of drones

We know that the patterns of dragons are the most complex in many patterns of drones, complex patterns require the highest number of drones, So our team's dragon pattern determines the best number of drones: So we chose different numbers of drones to draw the drawing. The principle of drawing was based on 4.1, and the result was shown as follows:

300 drones renderings
400 drones renderings

500 drones renderings

As can be seen from the above diagram, it is not hard to find that the effect of the drone is not obvious when the number of unmanned aerial vehicles exceeds 600 . Therefore, we directly select 500-600 drones to complete our performance needs. And it doesn't waste resources.

### 4.2.2 The imaging effect of the third image

We use 500 drones to show the drone pattern of the third image, which is the panda, as shown below:

Fig9 Panda final image
We painted the colors of the bamboo green, and the color of the panda was painted red to make it look better.

### 4.3 Flight range

The number of Drones is $n$, which changes as the image changes.

$$
\begin{aligned}
& x_{\max }-x_{\min }=\text { horizontal distance } \\
& y_{\max }-y_{\min }=\text { vertical distance }
\end{aligned}
$$

We can calculate the maximum performance area due to certain plotting scale and horizontal and vertical distance.

Calculate the distance of complex graph
The distance between the $\mathrm{i}^{\text {th }}$ pixel and ( $\left.\mathrm{i}-1\right)^{\text {th }}$ pixel is di. We calculate every distance between two neighboring pixels, guaranteeing the smallest distance among all as safe distance- 2 m .
Calculating the number of pixels ( $\mathrm{x}, \mathrm{y}$ ),
$\mathrm{x} / \mathrm{min}(\mathrm{di})=$ the length of performing region/safety distance
$y / \min (d i)=$ the width of performing region/safety distance
Calculate the distance of simple graph
Ferris wheel's radius is 1 and it has 60 points. The distance of every two points is 1/60.
$1: 2 \pi=$ performance areas/ safe distance

Fig10
We can see that the fourth image has the biggest area of demand, because the fourth image is more than complex and it has some protruding regions that are so concentrated. Based on this conclusion, we know that we need to avoid designing this kind of image in the future creation.

Different areas for graphs:
17300501002680016020047585.3333321789334004506637211 .23779

Security factors
The error of GPS will lead the Drones to crash and cause malfunction of the Drone system so that it threatens the security of audiences.

## 4. 4 View angle

### 4.4.1 Plan to 3D graph

The drone show performs in the sky, so that people need to raise their heads to watch the show. In order to maximize the performance effect, we incline the Drone array to certain degrees. According to knowledge related to human mechanics, the suitable angle is around 30 degrees, which is the incline angle value of the Drone array as $\theta$. The distance between audiences and performance region is L in meters. The height of the Drone array is depicted as ( $\mathrm{L}, \theta$ ). With certain length of L , we can determine the height of each Drone from the equation:

$$
\mathrm{h}=\mathrm{L} * \tan (90-\theta)
$$

The coordinate of every Drone in the 3-dimension is $(\mathrm{x}, \mathrm{y}, \mathrm{z})$.

$$
\left\{\begin{array}{c}
x_{0}=x \cdot \sin \theta \\
y_{0}=y \\
z_{0}=x \cdot \cos \theta+h
\end{array}\right.
$$

Fig 11
The figure shows the perspective of the audiences to the Drone arrays.

### 4.5 Performance time

In order to determine the total time of the performance time, we can divide the time into several portions, $T_{1}$ for the time that Drones flying from the ground to the sky; $T_{2}$ for the rotation time in the sky; $T_{3}$ for the different graphs changing time; and $T_{4}$ for the landing time. Assume that there are $x$ batches of Drones flying from the ground to the sky, and the flight distance of the $i^{\text {th }}$ Drone is $L_{i}$, and $L_{i j}$ shows the partial distance during the $\mathrm{T}_{j}$ period such as $L_{i l}$ is the departure time, the $L_{i 2}$ is the changing time, and $\left(x_{i 1}, y_{i l}\right)$ and $\left(x_{i 2}, y_{i 2}\right)$ illustrates the Drone's initial position on the ground and the position in the sky. More specifically, the departure time can be subdivided into the time that Drones fly vertically to the sky and the shaped time. Define $L_{i 1}^{0}$ and $L_{i 1}^{1}$ as each flight distance during the first process. The equation can be deduced following,

$$
\begin{gathered}
L_{i 1}^{0}=h_{i} \\
L_{i 1}^{1}=\sqrt{\left(x_{i 1}+x_{i 2}\right)^{2}+\left(y_{i 1}+y_{i 2}\right)^{2}} \\
L_{i 1}=L_{i 1}^{0}+L_{i 1}^{1} \\
t_{i}^{\text {total }}=\frac{L_{i 1}}{v_{0}} \\
t_{i 1}^{\text {total }}=t_{i 1}^{0}+t_{i 1}^{1}
\end{gathered}
$$

where $v_{0}$ is the constant velocity of the Drone flying vertically to the sky. Therefore, $T_{1}$ can be derived:

$$
T_{1}=\frac{\left(h_{i}+\sqrt{\left(x_{i 1}+x_{i 2}\right)^{2}+\left(y_{i 1}+y_{i 2}\right)^{2}}\right)}{v_{0}}
$$

About the rotation time, we just need to consider the rotation time of the outermost points because require the longest time for rotation. Assume that the center of the rotation is the origin, then the equation:

$$
T_{2}=\frac{\max \left(\sqrt{x_{i}^{2}+y_{i}^{2}}\right)}{v_{\max }}
$$

where $v_{\max }$, which is the largest velocity, is the outermost points' velocity, determined by the Drones' Product parameters and manipulators. And the angular velocity $\omega$ of whole system can be determined by:

$$
\omega=\frac{2 \pi}{T_{2}}
$$

Moreover, the changing time actually has been expressed in the $T_{1}$

$$
T_{3}=t_{i 1}^{\text {total }}-t_{i 1}^{0}=t_{i 1}^{1}
$$

For the landing time, it is equal to the take-off period,

$$
T_{4}=T_{1}
$$

By parameterizing every time period and assuming that the number of the performing pattern is $n$, the total time of whole aerial light shows can be expressed as following :

$$
\begin{aligned}
& \mathrm{T}=T_{1}+n \cdot T_{2}+(n-1) \cdot T_{3}+T_{4} \\
& T=T 1+T 2+T 3 \\
& t 1=\frac{2 \times\left(h_{i}+\sqrt{\left(x_{i 1}+x_{i 2}\right)^{2}+\left(y_{i 1}+y_{i 2}\right)^{2}}\right)}{v_{0}}+ \\
& t 2 \frac{n \times \max \left(\sqrt{x_{i}^{2}+y_{i}^{2}}\right)}{v_{\max }}+ \\
& t 3 \frac{(n-1) \times \sqrt{\left(x_{i 1}+x_{i 2}\right)^{2}+\left(y_{i 1}+y_{i 2}\right)^{2}}}{v_{0}}
\end{aligned}
$$

Because the speed of the UAV can not be determined, so we can not find the specific time, can only be based on some video and World Fly-in Expo summarized results, 3 patterns of performance can last about 10 minutes, if it lasts for 30 minutes, you need to prepare 10 patterns.

## 5 Model examination

In order to check the accuracy and range of the model, we choose more graphs to calculate this model.
国中
CHINA

Fig 12
Put above graph into Matlab, and stipulate to use 500 drones. We can finally get the following image:

Fig 13
According to above figures, we can conclude:
When we deal with some pictures which have smooth edge, such as fronts and pandas, our model can work well. However, when we address the rough graph like dragon, it does not have great effect. Consequently, we need to avoid choosing pictures with rough edge. If we need to deal with such kind of pictures, those edges need to be polished.

## 6 Error check

According to the previous, we can know that drones can make some errors
because of the GPS positioning error. Therefore, we can know the error range is 1 meter or 1 to 3 meters from previous section. We choose the accurate GPS and GALILEO binary positioning to check error for drones, which means the error range is 1 meter.

We choose the image of 3th image (Padan), and the corresponding distribution is matrix $\mathrm{t} 1, \mathrm{t} 2$, and t 3 . We randomly decrease or increase $\Delta \mathrm{L}$ of elements in the matrix t 1 , t 2 , and t 3 . $\Delta \mathrm{L}$ conforms to the randomly arrangement: and we will get the new matrix as well as turn it into the following image:

Fig 14
According to the comparison images above, we can find that even though there are errors. For fig 14, the images can be recognized. However, for fig 14, it's relatively harder to recognize the image. There are the main reasons: in fig 14, the curve distribution of the edge of the image is disperse; the curve distribution of edge of the image is concentrated for fig 14 . In order to decrease the impact caused by the system error, we need to disperse the concentrated curve. Our conjectural solution plans are 1. Improve the technology of GPS and reduce the errors. 2. Increase the number of the drones and expand the image. 3. Expand the images directly, including expansion of the center of the image as original point proportionally due to the size of the drones.

Furthermore, solution plan 1 is limited by the technology, and solution plan 2 and solution plan 3 are shown below:

Fig 15
According to the images shown above, solution plan 3 is better than solution plan 2. Therefore, we can employ any of them. The advantages and disadvantages are that
solution plan 2 needs more drones and requires more cost; solution plan 3 is too diverse to make the figure clear enough without sufficient light.

## 7 Model evaluation

## Advantages

This model could get the arrangement of the drones with any given number as soon as people draw the image that they want.

- This model could determine the location and arrangement of the drones with any given number, and according to the distribution image, we can get the most suitable number of the drones directly.
- This model avoids calculating the length of the edges of complex images directly, instead calculating the number of pixels and their locations.

## Disadvantages

- When we deal with the keen and slender figure such as the tendrils of the dragon and the back of the dragon, it easily causes the congestion of drones. Our models cannot give the better resolution, and the only way to solve this is disposing the previous figure artificially.
- Our models have the high standard of figure's edge. If the image is too wide, the possibility of two edges will come. Our models do with this problem by using Image processing software to reduce the size of pixels at present.
All in all, the advantages of this model are the accuracy, convenience, and the diversity of the results. However, the requirement for the images is high-standard.

## A letter

Dear mayor ：
How are you，it＇s an honor to be able to design a＂Drone Clusters as Sky Light Displays＂for our city．Our team four people after 36 hours of research，and our team made a preliminary preparation for the lighting performance of the drone cluster．We went to Wuhan，China to watch the drones show of the world flight conference． Finally，we come to the following conclusions：drone performance is very beautiful， in the performance process，the drone can rotate around the center，so that the audience in different directions can see the best effect of the image，So in our city＇s drone cluster lighting show，the choice of the site can be for all directions，for more people to watch，such as parks and other areas．

Our model runs very well，and can be applied to different patterns，different numbers of drones，as long as you give different patterns you want，and the budget of the funds，we can achieve what you want，In this paper，we selected three images： Ferris wheel，dragon and Chinese characters to show．If you want more image display， you can run the code in the appendix，and you can get．
Here are three renderings of the pattern，the background after PS handle，it is easier to see the night sky effect：

Here are the effects of different numbers of drones（（page limited，only show the 400／600／800／1000 drones effect，respected mayor，you can overall consider the drone performance and drone performance price two aspects，the higher the price，the more the number of drones，but the better the display effect ）：

600 无人机效果图

800 无人机效果图

1000 无人机效果图

Other matters needing attention in drones performance：
（1）If 500 drones are selected to perform，the performance area of the drone is about 300 meters long and 200 meters wide，while the drone performance area should be isolated to prevent the audience march into the arena．
（2）The lighting and pattern effects of the drone can be changed，but try to make the edges smoother．
（3）The drones performance of the three patterns is shorter and we expect to be within 10 minutes．According to the drone performance in other areas，they prepared a lot of patterns，about 10－20，lasting for 30 minutes or even longer．
（4）During the drone performance，too many streetlights should be avoided in the acting area so as not to affect the performance．

So，from our team＇s observation on the＂drone show＂，Not only has it impacted our vision，but also more of our progress in science and technology，In the future，we hope to encourage some students to apply their knowledge to practical life．Cultivate practical ability to push our other technologies to a higher level．We also learn a lot during this practice，and we hope that we should do air light show．
